of each year's
precipitation
historically fell
on days with
average
temperatures
just below
freezing?*

“Rain vs Snow”

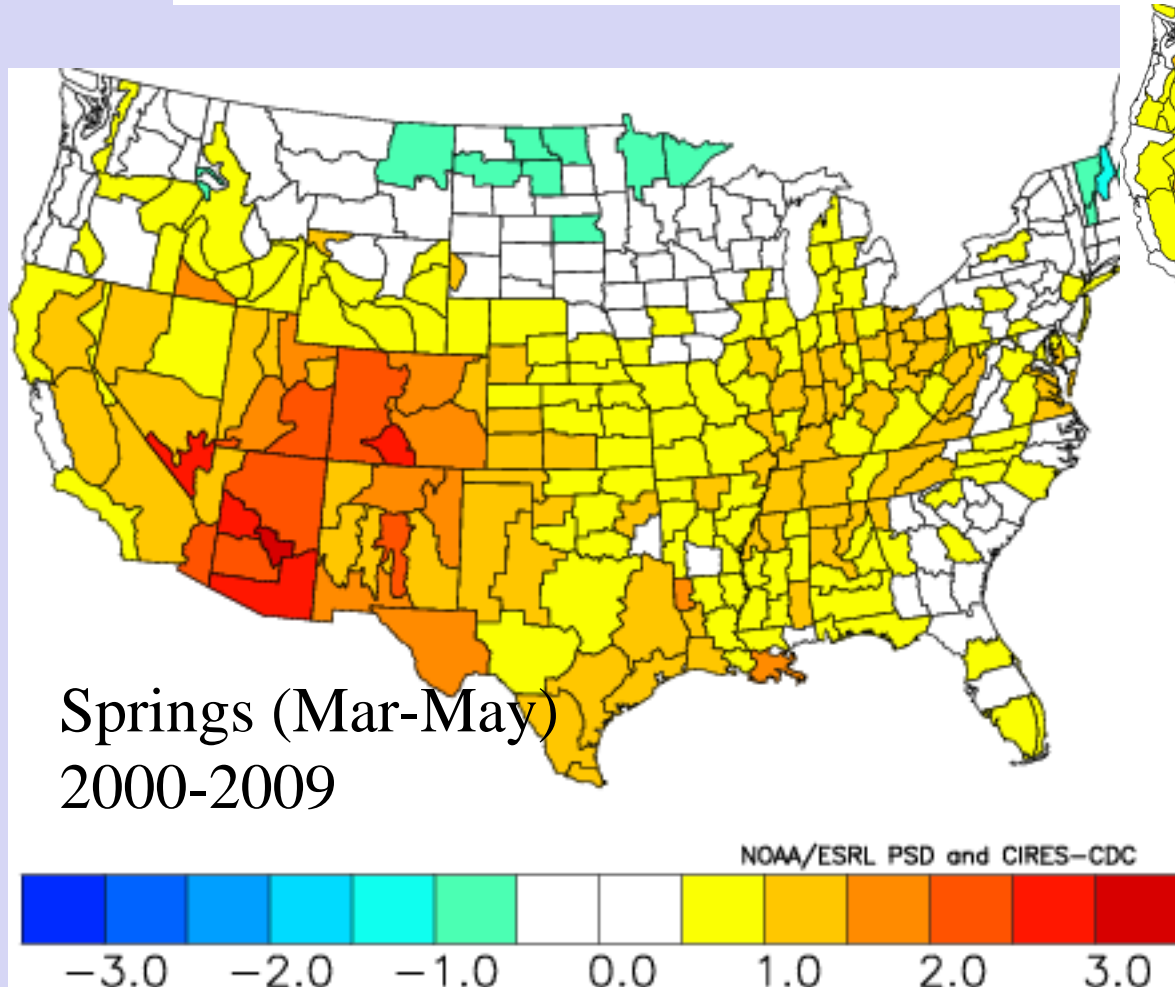

*Computed by Mike Dettinger from gridded
historical US weather data (from Bates et al, in
rev)*

During recent history, temperature changes in the western U.S. have tracked those in global temperature

Here is the pattern of warming since 2000.

Deviation from 1971-2000 average temperatures:

Springs (Mar-May)
2000-2009

Annual (Sep-Aug)
2000-2009

Degrees F

Barnett et al., Science, 2008 → Formal detection & attribution of the combination of changes in

- winter temperature
 - SWE/P
 - streamflow timing
- ## to greenhouse origins!

When did detection
become possible?

Global Atmospheric CO₂ Concentration (ppmv) and Carbon Emissions (GtC)

Historical Emissions from Fossil-Fuel Burning, Cement Manufacture, and Gas Flaring
SRES Emissions from Fossil-Fuel Burning and other CO₂

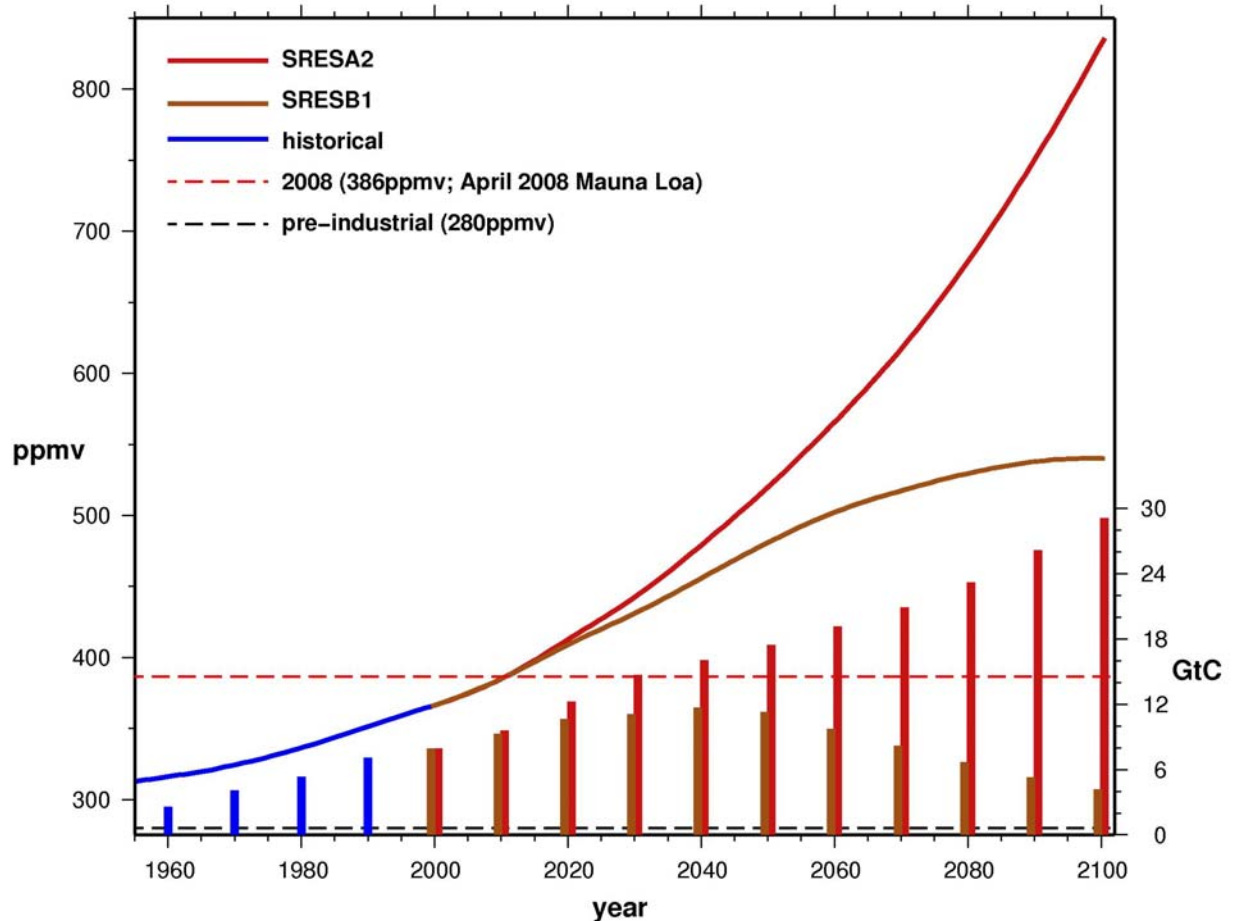

Figure 2. Global carbon emissions (GtC), shown by bars, and CO₂ concentrations (ppmv), shown by lines, for historical period (blue) and for SRES B1 (brown) and SRES A2 (red) emissions scenarios. Pre-industrial and present day CO₂ concentrations indicated by gray and mauve dashed lines.

ppmv: parts per million by volume

GtC: Gigatons of Carbon, 1 GtC corresponds to ~3.67 Gt CO₂

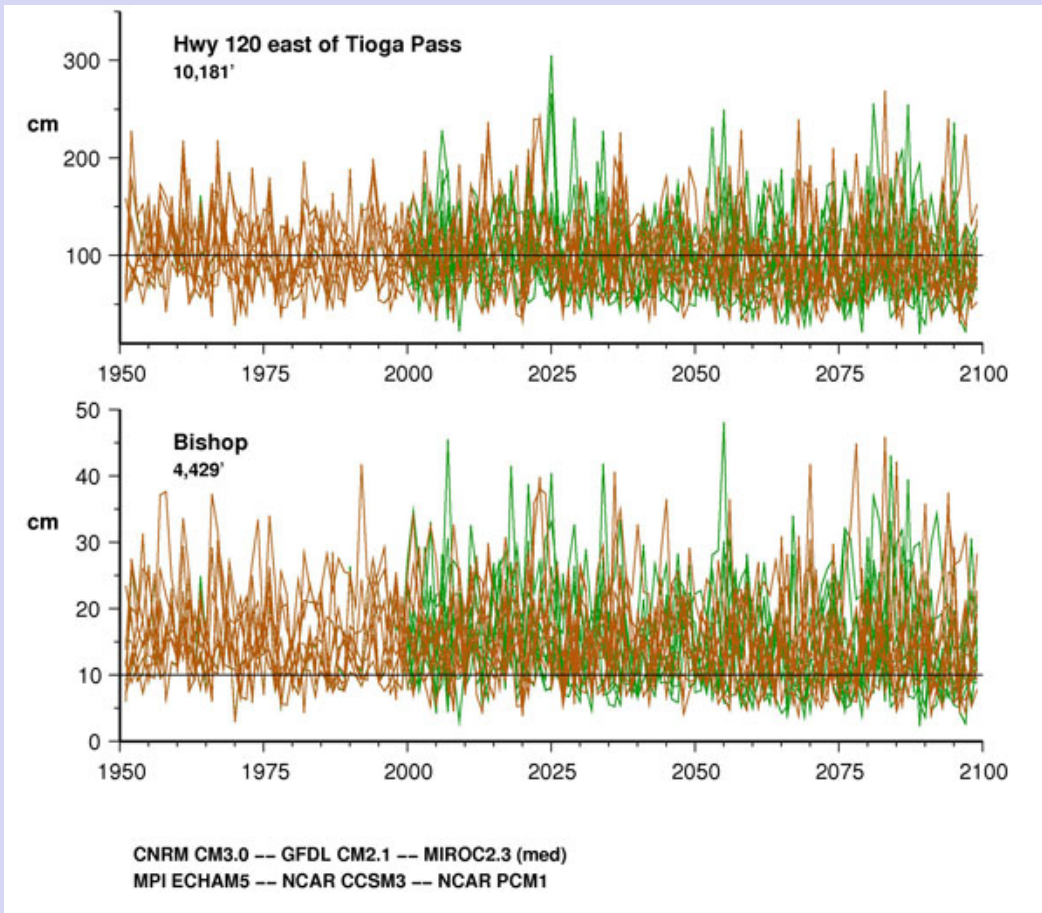

All simulations warm over the 21st Century, at very substantial rates
A2 simulations (red) warm more than B1 simulations (blue)

hydrological model

hi sierra apr 1 swe

BCSD (1950–2099; 6 gcms)

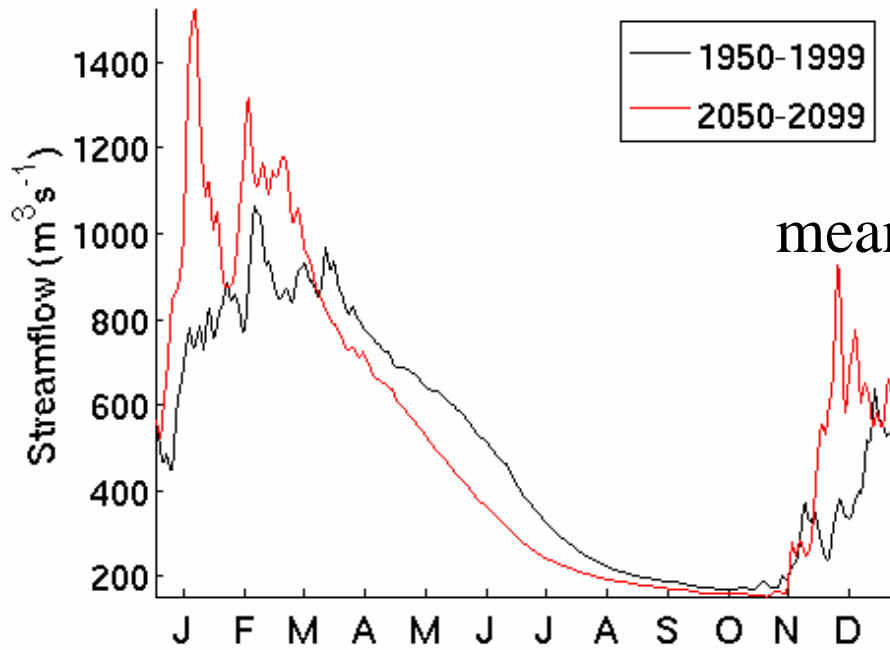

by 2050, occurrences of cases with minimal Sierra Nevada spring SWE is much more frequent, especially in A2 scenario simulations

Snow Accumulation (April 1) CNRM A2
10th percentile years (1961-1990) shown in red

Northern Sierra Nevada (cnrmcm3,sresa2)

mean hydrographs CNRM A2
Northern Sierra becomes
more flood-prone

99th percentile streamflow events come twice as often

OBSERVATIONS AND MODELS INDICATE:

The West's water supply is vulnerable to climate changes and weather extremes.

Humans have altered atmospheric composition and thus are altering the earth's climate; GH gases have long lifetimes, so choices made now and in future will greatly impact future climate.

The West has already seen signs of warmer winter storms, more rain, less snow, and earlier spring snowmelt. A substantial portion of these changes appear to be attributable to anthropogenic warming. More warming is very likely in future decades.

Recent IPCC model projections for western precipitation are scattered, but *several* show moderate drying as tends to be characteristic of Mediterranean regions globally. A reduction in precipitation is amplified into even greater reduction in soil moisture and runoff in the more arid basins of the West.

Research on downscaling is yielding climate projections of regional, local measures suitable for hydrologic model simulations. Ensembles are available from which uncertainties can be explored.
